

DP-304592

REAR STEERING SENSOR DIAGNOSTIC ALGORITHM FOR FOUR-WHEEL STEERING SYSTEMS

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of United States Provisional Application No. 60/309,434, filed August 1, 2001, the contents of which are incorporated by reference herein in their entirety.

BACKGROUND

[0002] In vehicular applications, a typical four-wheel steering system steers the front and the rear wheels of a vehicle. More specifically, a rear-wheel steering portion of the system may produce a desired rear-wheel steering angle to improve maneuverability at low speeds. The low speed steering method may achieve tight turning radii at low speeds by steering the front and rear wheels in different directions to thereby reduce the effective turning radius of the vehicle. In the rear-wheel steering portion of a four-wheel steering system, an electric motor is typically employed to steer the rear wheels. The position of the rear steering mechanism may be determined with a sensor.

SUMMARY

[0003] The above described and other features are exemplified by the following Figures and Description in which a vehicular diagnostic system is disclosed that controls the rear steering angle of a vehicle by receiving a plurality of signals indicative of rear steering angle; checking at least one of the plurality of signals to determine if it falls within a valid range; correlating at least a first signal of the plurality of signals with at least a second signal of the plurality of signals to determine if either the first signal or the second signal is invalid; and rejecting any signals found to be invalid.

DP-304592-1

[0008] FIG. 4 is a flow diagram illustrating a method for controlling the rear steering angle of the four-wheel steering system of FIG. 1.

[0011] The front steering mechanism 14 comprises a rack shaft 20, a rack 22 disposed intermediately between opposing ends of the rack shaft 20, a tie rod 24 disposed on each opposing end of the rack shaft 20, a knuckle arm 26 connected to each tie rod 24, and a front steerable wheel 28 rotatably disposed on each knuckle arm 26. The rack shaft 20, tie rods 24, and knuckle arms 26 are configured such that the front steerable wheels 28 can pivot in unison relative to the vehicle to steer or to effect a change in the direction of travel while the vehicle is moving.

[0012] The front steering mechanism 14 further comprises a mechanism through which a vehicle operator can effectuate a desired change in the direction of travel of the vehicle. Such a mechanism comprises a steering column 30 disposed in operable communication at one end with the rack 22 through a pinion 32 and at an opposing end thereof with a steering device 34. The steering device 34 may be a hand steering wheel, or "hand-wheel". Manipulation of the steering device 34, i.e., rotation of the hand-wheel, causes the axial rotation of the steering column 30, which in turn causes the rotation of the pinion 32. Rotation of the pinion 32, through the engagement of the rack 22 and the pinion 32, effectuates the lateral translation of the rack 22 relative to the vehicle. The lateral translation of the rack 22 causes the front steerable wheels 28 to angle relative to the vehicle, thereby altering the direction of travel while the vehicle is moving.

[0013] The rear steering mechanism 16 comprises a rack shaft 36, a rack 38 disposed intermediately between opposing ends of the rack shaft 36, tie rods 40 disposed on each opposing end of the rack shaft 36, a knuckle arm 42 connected to each tie rod 40, and a rear steerable wheel 44 rotatably disposed on each knuckle arm 42. The rack shaft 36, tie rods 40, and knuckle arms 42 are configured such that rear steerable wheels 44, like the front steerable wheels 28, can be pivoted in unison relative to the vehicle to steer the vehicle upon lateral translation of the rack 38.

[0014] The rear steering mechanism 16 further comprises a mechanism through which the rear steerable wheels 44 can similarly be pivoted. Such a mechanism comprises a motor 46 operably connected to the rack 38 through a drive mechanism 48. The drive mechanism 48, through a pinion 49, transfers the rotational motion of a rotor shaft 47 of the motor 46 to linear motion of the rack 38, which effectuates the lateral motion of the rack shaft 36 and, ultimately, the pivoting of the rear steerable wheels 44.

[0015] The vehicle is further provided with a steering sensor 50 for detecting an angular position of the steering column 30, a vehicle speed sensor 52, and a rear rack shaft displacement sensor 58. The rear rack shaft displacement sensor 58 detects the displacement of its corresponding rack shaft 36 from a reference position, which is the position in which each rear steerable wheel 44 is aligned and rotatable.

[0017] In order to perform the prescribed functions and desired processing, as well as the computations therefore (e.g., the execution of the rear-wheel steering algorithms, and the like), the controller 18 may include, but need not be limited to, processors, computers, memory, storage, registers, timing devices, interrupts, communication interfaces, input/output signal interfaces, and the like, as well as combinations comprising at least one of the foregoing. For example, the controller 18 may include input signal filtering to enable accurate sampling and conversion or acquisition of such signals from communications interfaces.

[0019] As shown in FIG. 3, a table 66 indicates exemplary values for signal-1 and signal-2 for rear-wheel angles between about negative 540 degrees and positive 540 degrees. The rear-wheel angle may be resolved to the accuracy of the potentially higher resolution signal (signal-2) by selection of the window range corresponding to the value of the potentially lower resolution signal (signal-1). Thus, this strategy protects the system from providing an

unintended rear steer for conditions of the sensor's signal-1 and signal-2 being shorted to each other, ground or battery, and from open circuit conditions.

[0020] Turning now to FIG. 4, a rear sensor correlation function is indicated generally by the reference numeral 70. The inputs from the sensor are signal-1 and signal-2, which typically vary with time. The function 70 includes a decision block 71 for determining whether the value of the second rear-wheel angle signal (signal-2) is within a valid range by checking that signal-2 is less than a valid maximum value of 4.925V and greater than a valid minimum value of 0.075V. It may be understood by those of ordinary skill in the pertinent art, that this and other valid ranges may be adjusted in order to meet design criteria. For example, an alternate exemplary embodiment may have a valid range for signal-1 of 0.25 Volts to 4.75 Volts, and a valid range for signal-2 of 0.5 Volts to 4.5 Volts.

[0021] If signal-2 is not within the valid range, typically indicating that a short to battery or a grounded output has occurred, a function 73 produces a signal indicative of a rear sensor signal-2 out-of-range fault. If, on the other hand, signal-2 is determined to be within a valid range, control is passed to a decision block 72 for determining whether the value of the first rear-wheel angle signal (signal-1) is less than its value at a first inflection point of the second rear-wheel angle signal.

[0022] The first inflection point is the first and lowest of four consecutively enumerated inflection points between the uniquely resolvable rear-wheel angles of +/- 405 degrees. In this exemplary embodiment, the four inflection points correspond to RWA1 signal voltage values of 1.0V, 2.0V, 3.0V and 4.0V, respectively. If the first value of signal-1 is less than its value at the inflection point, then the position corresponding to the second rear-wheel angle signal (signal-2) is determined by function 74 by subtracting a second rear-wheel angle center value from the second rear-wheel angle signal (signal-2), multiplying the difference by a scale factor to convert volts to degrees, and adding a second rear-wheel angle offset corresponding to the first inflection point.

[0023] The second rear-wheel angle center value is determined during an initial wheel alignment, at which time both signal-1 and signal-2 will typically approach 2.5 volts. Accordingly, the center value will typically

approach zero degrees or 2.5 volts, but may be some value other than zero degrees due, for example, to tolerances in the build and/or mechanical installation of a given vehicle. If, on the other hand, the condition of decision block 72 is false, then a decision block 76 determines whether the value of the first rear-wheel angle signal (signal-1) is less than its value at a second inflection point, -90 degrees here, of the second rear-wheel angle signal. If the first value of signal-1 is less than its value at the second inflection point, then the position corresponding to the second rear-wheel angle signal (signal-2) is determined by function 78 by subtracting a second rear-wheel angle center value from the second rear-wheel angle value, multiplying the difference by a scale factor, and adding a second rear-wheel angle offset corresponding to the second inflection point. The sign of the scale factor alternates for adjacent windows, and is about $-180/4.5$ for windows -2, 0, and 2; and $+180/4.5$ for windows -1 and 1 in this exemplary embodiment.

[0024] The offsets corresponding to the inflection points are -360, -180, 0, 180 and 360 degrees, respectively. For example, if the actual rear-wheel angle is negative 180 degrees, signal-1 should be about 1.5V (see FIG. 2) corresponding to signal window(-1) (see FIG. 3) and signal-2 (RWA2) should be about 2.5V (see FIG. 2), so block 78 would calculate the rear-wheel angle position based on the RWA2 signal to be $(RWA2 - RWACenterValue) * Scale + RWA_OFFSET2 = (2.5 - 2.5) * (180 / 4.5) + (-180) = -180$ degrees. For an actual rear-wheel angle of negative 200 degrees, signal-1 should be about 1.4V (see FIG. 2) corresponding to signal window(-1) (see FIG. 3) and signal-2 (RWA2) should be about 2V (see FIG. 2), so block 78 would calculate the rear-wheel angle position based on the RWA2 signal to be $(RWA2 - RWACenterValue) * Scale + RWA_OFFSET2 = (2 - 2.5) * (40) + (-180) = -200$ degrees.

[0025] If the condition of decision block 76 is false, then a decision block 80 determines whether the value of the first rear-wheel angle signal (signal-1) is less than its value at a third inflection point of the second rear-wheel angle signal. If the first value of signal-1 is less than its value at the inflection point, then the position corresponding to the second rear-wheel angle signal (signal-2) is determined by function 82 by subtracting a second rear-wheel angle center value from the second rear-wheel angle value, multiplying

[0026] If the condition of decision block 80 is false, then a decision block 84 determines whether the value of the first rear-wheel angle signal (signal-1) is less than its value at a fourth inflection point of the second rear-wheel angle signal. If the first value of signal-1 is less than its value at the inflection point, then the position corresponding to the second rear-wheel angle signal (signal-2) is determined by function 86 by subtracting a second rear-wheel angle center value from the second rear-wheel angle value, multiplying the difference by a scale factor, and adding a second rear-wheel angle offset corresponding to the fourth inflection point.

[0028] A decision block 90 is used for determining whether the value of the first rear-wheel angle signal (signal-1) is within a valid range by checking that signal-1 is less than a valid maximum value of 4.925V and greater than a valid minimum value of 0.075V. If signal-1 is not within the valid range, typically indicating that a short to battery or a grounded output has occurred, a function 92 produces a signal indicative of a rear sensor signal-1 out-of-range fault. If, on the other hand, signal-1 is determined to be within a valid range, the position corresponding to the first rear-wheel angle signal is determined by function 94 by subtracting a first rear-wheel angle center value from the first rear-wheel angle value, and multiplying the difference by a scale factor and control is passed to the decision block 72, described above.

[0029] Thus, the rear-wheel signal correlation diagnostics compare the first signal (“signal-1”) with the second signal (“signal-2”). Since signal-2 is a saw tooth waveform, a particular value of signal-2 does not absolutely determine the exact angle value. Depending on the value of rear sensor signal-1, five regions for the rear sensor signal-2 are defined by four inflection points, as follows: RWA2_INFLECT_PT1 =1.00 V; RWA2_INFLECT_PT2 =2.00 V;

RWA2_INFLECT_PT3 = 3.00 V; and RWA2_INFLECT_PT4 = 4.00 V, respectively, for the first through fourth inflection points.

[0030] An angle offset corresponding to each region defined by the inflection points has to be added to the relative value of signal-2, and is determined based on each region as follows: RWA2_OFFSET1 = -360 sensor degrees; RWA2_OFFSET2 = -180 sensor degrees; RWA2_OFFSET3 = 0 sensor degrees; RWA2_OFFSET4 = 180 sensor degrees; and RWA2_OFFSET5 = 360 sensor degrees, respectively, for the first through fifth regions.

[0031] Once the rear position value is calculated for each of signal-1 and signal-2, as discussed above, the rear sensor correlation diagnostic determines whether the two signals correlate by comparing the signals and determining that they each correlate or fall within a predetermined threshold tolerance of each other, such as, for example, within 40 degrees of each other. Thus, the diagnostic will be triggered when the comparison value is above the threshold tolerance, or above 40 degrees in this exemplary embodiment.

[0032] Accordingly, the four-wheel steering system 10 uses the rear sensor 58 mounted on the pinion to measure the absolute position of the rear wheels. The rear sensor provides two signals; signal-1 may be used for initialization, and signal-2 may be used for more accurate measurement. If the sensor signals were intermittent, shorted to ground, shorted to battery, shorted to each other or open, it might cause the reading to be corrupted and hence the rear-wheel angle estimation to be incorrect. This diagnostic algorithm will detect any of these conditions, thus preventing an unintended steer.

[0033] The above-described methodology provides a diagnostic algorithm for detecting erroneous rear-wheel steering angle signals. In addition, the present teachings may be embodied in the form of computer-implemented processes and apparatuses for practicing those processes. The present teachings can also be embodied in the form of computer program code containing instructions embodied in tangible media, such as floppy diskettes, CD-ROMs, hard drives, or any other computer-readable storage media, wherein, when the computer program code is loaded into and executed by a computer, the computer becomes an apparatus for practicing the teachings of the present disclosure.

[0034] The teachings of the present disclosure can be embodied in the form of computer program code, for example, whether stored in a storage medium 100 communicated with controller 18, loaded into and/or executed by a computer, or as data signal transmitted, whether by a modulated carrier wave or not, over some transmission medium, such as over electrical wiring or cabling, through fiber optics, or via electromagnetic radiation, wherein, when the computer program code is loaded into and executed by a computer, the computer becomes an apparatus for practicing the teachings herein. When implemented on a general-purpose microprocessor, the computer program code segments configure the microprocessor to create specific logic circuits.

[0035] While the disclosure has been made with reference to exemplary embodiments, it will be understood by those of ordinary skill in the pertinent art that various changes may be made and equivalents may be substituted for the elements thereof without departing from the scope of the present disclosure. In addition, numerous modifications may be made to adapt the teachings of the disclosure to a particular object or situation without departing from the essential scope thereof. Therefore, it is intended that the Claims not be limited to the particular embodiments disclosed as the currently preferred best modes contemplated for carrying out the teachings herein, but that the Claims shall cover all embodiments falling within the true scope and spirit of the disclosure.
